# Brownian excursions in a corridor and related Parisian options 

Angelos Dassios ${ }^{\dagger}$, Shanle Wu*<br>${ }^{\dagger *}$ Department of Statistics, London School of Economics Houghton Street, London WC2A 2AE<br>${ }^{\dagger}$ a.dassios@lse.ac.uk<br>*s.wu3@lse.ac.uk

#### Abstract

In this paper, we study the excursion time of a Brownian motion with drift inside a corridor by using a four states semi-Markov model. In mathematical finance, these results have an important application in the valuation of options whose prices depend on the time their underlying assets prices spend between two different values. In this paper, we introduce the Parisian corridor option and obtain an explicit expression for the Laplace transform of its price formula.

Keywords: excursion time, four states Semi-Markov model, Parisian corridor options, Laplace transform.

## 1 Introduction

The concept of Parisian options was first introduced by Chesney, JeanblancPicque and Yor [6]. It is a special case of path dependent options. The owner of a Parisian option will either gain the right or lose the right to exercise the option upon the price reaching a predetermined barrier level $L$ and staying above or below the level for a predetermined time $D$ before the maturity date $T$. More precisely, the owner of a Parisian down-and-out option loses the option if the underlying asset price $S$ reaches the level $L$ and remains constantly below this level for a time interval longer than $D$. For a Parisian down-and-in option the same event gives the owner the right to exercise the option. For details on the pricing of Parisian options see [6], [14], [16] and [13].

The Parisian corridor options replace the barrier by a corridor. Instead of considering the excursion above or below a barrier, we consider the excursions inside a corridor. For example, the owner of a Parisian corridor in option gains the option if the underlying asset price process $S$ has an excursion in the corridor for longer than $d$ before the maturity of the option. For the pricing of the Parisian options whose prices depends on the excursion outside a corridor
see [10]. Later on, we will give the Laplace transforms which can be used to price this type of options.

In this paper, we are going to use the same definition for the excursion as in [6] and [7]. Let $S$ be a stochastic process and $l_{1}, l_{2}, l_{1}>l_{2}$ be the level of two barriers forming the corridor. We define

$$
\begin{equation*}
g_{l_{i}, t}^{S}=\sup \left\{s \leq t \mid S_{s}=l_{i}\right\}, \quad d_{l_{i}, t}^{S}=\inf \left\{s \geq t \mid S_{s}=l_{i}\right\}, \quad i=1,2 \tag{1}
\end{equation*}
$$

with the usual conventions, $\sup \{\emptyset\}=0$ and $\inf \{\emptyset\}=\infty$. Assuming $d_{i}>0$, $i=1,2,3,4$, we now define

$$
\begin{gather*}
\tau_{1}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{S_{t}>l_{1}\right\}}\left(t-g_{l_{1}, t}^{S}\right) \geq d_{1}\right\},  \tag{2}\\
\tau_{2}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{l_{2}<S_{t}<l_{1}\right\}} \mathbf{1}_{\left\{g_{l_{1}, t}^{S}>g_{l_{2}, t}^{S}\right\}}\left(t-g_{l_{1}, t}^{S}\right) \geq d_{2}\right\},  \tag{3}\\
\tau_{3}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{l_{2}<S_{t}<l_{1}\right\}} \mathbf{1}_{\left\{g_{l_{1}, t}^{S}<g_{l_{2}, t}^{S}\right\}}\left(t-g_{l_{2}, t}^{S}\right) \geq d_{3}\right\},  \tag{4}\\
\tau_{4}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{S_{t}<l_{2}\right\}}\left(t-g_{l_{2}, t}^{S}\right) \geq d_{4}\right\},  \tag{5}\\
\tau^{S}=\tau_{2}^{S} \wedge \tau_{3}^{S} . \tag{6}
\end{gather*}
$$

We can see that $\tau_{2}^{S}$ is the first time that the length of the excursion in the corridor reaches the given level $d_{2}$, given that this excursion starts from the upper barrier $l_{1} ; \tau_{3}^{S}$ corresponds to the one in the corridor with the given level $d_{3}$ starting from the lower barrier $l_{2}$; and $\tau^{S}$ is the smaller of $\tau_{2}^{S}$ and $\tau_{3}^{S}$. When we take $d_{2}=d_{3}=d, \tau^{S}$ is actually the the first time that the length of the excursion inside the corridor reaches given level $d$, which is what we want to study later on.

We can also see that $\tau_{1}^{S}$ is the first time that the length of the excursion of process $S$ above the barrier $l_{1}$ reaches given level $d_{1} ; \tau_{4}^{S}$ corresponds to the one below $l_{2}$ with required length $d_{4}$. Although $\tau_{1}^{S}$ and $\tau_{4}^{S}$ are not of our interest in this paper (see [10] for the pricing of the Parisian options depend on $\tau_{1}^{S}$ and $\tau_{4}^{S}$ ), we need to use these two stopping times to define our four states semi-Markov model.

Now assume $r$ is the risk-free rate, $T$ is the term of the option, $S_{t}$ is the price of its underlying asset, $K$ is the strike price, $Q$ is risk neutral measure. If we have a Parisian corridor out-call option with the barrier $l_{1}$ and $l_{2}$, its price can be expressed as:

$$
P C_{o u t-c a l l}=e^{-r T} E_{Q}\left(\mathbf{1}_{\left\{\tau^{S}>T\right\}}\left(S_{T}-K\right)^{+}\right)
$$

and the price of a Parisian corridor in-put option is:

$$
P C_{i n-p u t}=e^{-r T} E_{Q}\left(\mathbf{1}_{\left\{\tau \tau^{S}<T\right\}}\left(K-S_{T}\right)^{+}\right) .
$$

In this paper, we are going to study the excursion time inside the corridor using a semi-Markov model consisting of four states. By applying the model to
a Brownian motion, we can get the explicit form of the Laplace transform for the price of Parisian corridor options. One can then invert using techniques as in [14].

In Section 2 we introduce the four states semi-Markov model as well as a new process, the doubly perturbed Brownian motion, which has the same behavior as a Brownian motion except that each time it hits one of the two barriers, it moves towards the other side of the barrier by a jump of size $\epsilon$. In Section 3 we obtain the martingale to which we can apply the optional sampling theorem and get the Laplace transform that we can use for pricing later. We give our main results applied to Brownian motion in Section 4, including the Laplace transforms for the stopping times we defined by (6) for both a Brownian motion with drift, i.e. $S=W^{\mu}$, and a standard Brownian motion, i.e. $S=W$. In Section 5 we focus on pricing the Parisian corridor options.

## 2 Definitions

From the description above, it is clear that we are actually considering four states, the state when the stochastic process is above the barrier $l_{1}$ the state when it is below $l_{2}$ and two states when it is between $l_{1}$ and $l_{2}$ depending on whether it comes into the corridor through $l_{1}$ or $l_{2}$. For each state, we are interested in the time the process spends in it. We therefore introduce a new process

$$
Z_{t}^{S}= \begin{cases}1, & \text { if } S_{t}>l_{1} \\ 2, & \text { if } l_{1}>S_{t}>l_{2} \text { and } g_{l_{1}, t}^{S}>g_{l_{2}, t}^{S} \\ 3, & \text { if } l_{1}>S_{t}>l_{2} \text { and } g_{l_{1}, t}^{S}<g_{l_{2}, t}^{S} \\ 4, & \text { if } S_{t}<l_{2}\end{cases}
$$

We can now express the variables defined above in terms of $Z_{t}$ :

$$
\begin{gather*}
g_{l_{i}, t}^{S}=\sup \left\{s \leq t \mid Z_{s}^{S} \neq Z_{t}\right\},  \tag{7}\\
d_{l_{i}, t}^{S}=\inf \left\{s \geq t \mid Z_{s}^{S} \neq Z_{t}\right\},  \tag{8}\\
\tau_{1}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{Z_{t}^{S}=1\right\}}\left(t-g_{l_{1}, t}^{S}\right) \geq d_{1}\right\},  \tag{9}\\
\tau_{2}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{Z_{t}^{S}=2\right\}}\left(t-g_{l_{1}, t}^{S}\right) \geq d_{2}\right\},  \tag{10}\\
\tau_{3}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{Z_{t}^{S}=3\right\}}\left(t-g_{l_{2}, t}^{S}\right) \geq d_{3}\right\},  \tag{11}\\
\tau_{4}^{S}=\inf \left\{t>0 \mid \mathbf{1}_{\left\{Z_{t}^{S}=4\right\}}\left(t-g_{l_{2}, t}^{S}\right) \geq d_{4}\right\} . \tag{12}
\end{gather*}
$$

We then define

$$
\begin{equation*}
V_{t}^{S}=t-\max \left(g_{l_{1}, t}^{S}, g_{l_{2}, t}^{S}\right), \tag{13}
\end{equation*}
$$

the time $Z_{t}^{S}$ has spent in the current state. It is easy to see that $\left(Z_{t}^{S}, V_{t}^{S}\right)$ is a Markov process. $Z_{t}^{S}$ is therefore a semi-Markov process with the state space $\{1,2,3,4\}$, where 1 stands for the state when the stochastic process $S$ is above
the barrier $l_{1} ; 4$ corresponds to the state below the barrier $l_{2} ; 2$ and 3 represent the state when $S$ is in the corridor given that it comes in through $l_{1}$ and $l_{2}$ respectively.

For $Z_{t}^{S}$ the transition intensities $\lambda_{i j}(u)$ satisfy

$$
\begin{gather*}
P\left(Z_{t+\Delta t}^{S}=j, i \neq j \mid Z_{t}^{S}=i, V_{t}^{S}=u\right)=\lambda_{i j}(u) \Delta t+o(\Delta t)  \tag{14}\\
P\left(Z_{t+\Delta t}^{S}=i \mid Z_{t}^{S}=i, V_{t}^{S}=u\right)=1-\sum_{i \neq j} \lambda_{i j}(u) \Delta t+o(\Delta t) \tag{15}
\end{gather*}
$$

Define

$$
\bar{P}_{i}(\mu)=\exp \left\{-\int_{0}^{\mu} \sum_{i \neq j} \lambda_{i j}(v) \mathrm{d} v\right\}, \quad p_{i j}(\mu)=\lambda_{i j}(\mu) \bar{P}_{i}(\mu) .
$$

Notice that

$$
P_{i}(\mu)=1-\bar{P}_{i}(\mu)
$$

is the distribution function of the excursion time in state $i$, which is a random variable $U_{i}$ defined as

$$
U_{i}=\inf _{s>0}\left\{Z_{s}^{S} \neq i \mid Z_{0}^{S}=i, V_{0}^{S}=0\right\}
$$

Note that because the process is time homogeneous this has the same distribution as

$$
\inf _{s>0}\left\{Z_{t+s}^{S} \neq i \mid Z_{t}^{S}=i, V_{t}^{S}=0\right\}
$$

for any time $t$. We have therefore

$$
p_{i j}(\mu)=\lim _{\Delta \mu \rightarrow 0} \frac{P\left(U_{i} \in(\mu, \mu+\triangle \mu), Z_{U_{i}}^{S}=j\right)}{\triangle \mu} .
$$

Moreover, in the definition of $Z^{S}$, we deliberately ignore the situation when $S_{t}=l_{i}, i=1,2$. The reason is that we only consider the processes, which

$$
\int_{0}^{t} \mathbf{1}_{\left\{S_{u}=l_{i}\right\}} \mathrm{d} u=0, i=1,2 .
$$

Also, when $l_{1}$ and $l_{2}$ are the regular points of the process (see [5] for definition), we have to deal with the degeneration of $p_{i j}$. Let us take a Brownian Motion as an example. Assume $W_{t}^{\mu}=\mu t+W_{t}$ with $\mu \geq 0$, where $W_{t}$ is a standard Brownian Motion. Setting $x_{0}$ to be its starting point, we know its density for the first hitting time of level $l_{i}, i=1,2$ is

$$
p_{x_{0}}=\frac{\left|l_{i}-x_{0}\right|}{\sqrt{2 \pi t^{3}}} \exp \left\{-\frac{\left(l_{i}-x_{0}-\mu t\right)^{2}}{2 t}\right\}
$$

(see [4]). According to the definition of transition density, $p_{12}(t)=p_{21}(t)=$ $p_{l_{1}}(t)=0$ and $p_{34}(t)=p_{43}(t)=p_{l_{2}}(t)=0$, for $t>0$.

Figure 1: A Sample Path of $W_{t}^{(\epsilon)}$

In [9] in order to solve the similar problem, we introduced the perturbed Brownian motion $X_{t}^{(\epsilon)}$ with respect to the barrier we are interested in. We apply the same idea here, and construct a new process double perturbed Brownian motion, $Y_{t}^{(\epsilon)}, \epsilon>0$, with respect to barriers $l_{1}$ and $l_{2}$. Assume $W_{0}^{\mu}=l_{1}+\epsilon$. Define a sequence of stopping times

$$
\begin{aligned}
\delta_{0} & =0 \\
\sigma_{n} & =\inf \left\{t>\delta_{n} \mid W_{t}^{\mu}=l_{1}\right\} \\
\delta_{n+1} & =\inf \left\{t>\sigma_{n} \mid W_{t}^{\mu}=l_{1}+\epsilon\right\}
\end{aligned}
$$

where $n=0,1, \cdots$ (see Figure 1). Now define

$$
\left\{\begin{array}{lll}
X_{t}^{(\epsilon)}=W_{t}^{\mu} & \text { if } & \delta_{n} \leq t<\sigma_{n} \\
X_{t}^{(\epsilon)}=W_{t}^{\mu}-\epsilon & \text { if } & \sigma_{n} \leq t<\delta_{n+1}
\end{array}\right.
$$

Similarly, we then define another sequence of stopping times with respect to process $X_{t}^{(\epsilon)}$ and barrier $l_{2}$

$$
\begin{aligned}
\zeta_{0} & =0 \\
\eta_{n} & =\inf \left\{t>\zeta_{n} \mid X_{t}^{(\epsilon)}=l_{2}\right\} \\
\zeta_{n+1} & =\inf \left\{t>\eta_{n} \mid X_{t}^{(\epsilon)}=l_{2}+\epsilon\right\}
\end{aligned}
$$

where $n=0,1, \cdots$ (see Figure 2). Then define

Figure 2: A Sample Path of $X_{t}^{(\epsilon)}$

$$
\left\{\begin{array}{ll}
Y_{t}^{(\epsilon)}=X_{t}^{(\epsilon)} \quad & \text { if } \quad \zeta_{n} \leq t<\eta_{n} \\
Y_{t}^{(\epsilon)}=X_{t}^{(\epsilon)}-\epsilon \quad & \text { if } \quad \eta_{n} \leq t<\zeta_{n+1}
\end{array} .\right.
$$

The process $Y_{t}^{(\epsilon)}$ is actually a process which starts from $l_{1}+\epsilon$ and has the same behavior as the related Brownian Motion expect that each time when it hits the barrier $l_{1}$ or $l_{2}$, it will have a jump towards the opposite side of the barrier with size $\epsilon$ (see Figure 3).

From the definition, it is clear that $l_{1}$ and $l_{2}$ become irregular points for $Y_{t}^{(\epsilon)}$. Also $Y_{t}^{(\epsilon)}$ converges to $W_{t}^{\mu}$ with $W_{0}^{\mu}=l_{1}$ almost surely for all t. Therefore as we prove in [9], the Laplace transforms of the variables defined based on $Y_{t}^{(\epsilon)}$ converge to those based on $W_{t}^{\mu}$. As a result, we can obtain the results for the Brownian Motion by carrying out the calculation for $Y_{t}^{(\epsilon)}$ and take the limit as $\epsilon \rightarrow 0$.

For $Y_{t}^{(\epsilon)}$, we can define $Z^{Y}, \tau_{1}^{Y}, \tau_{2}^{Y}$ and $\tau^{Y}$ as above (we suppress $(\epsilon)$ on the

Figure 3: A Sample Path of $Y_{t}^{(\epsilon)}$
superscript). For $Z^{Y}$, we have the transition densities (see [4])

$$
\begin{align*}
& p_{12}(t)=\frac{\epsilon}{\sqrt{2 \pi t^{3}}} \exp \left\{-\frac{(\epsilon+\mu t)^{2}}{2 t}\right\}  \tag{16}\\
& p_{21}(t)=\exp \left\{\mu \epsilon-\frac{\mu^{2} t}{2}\right\} s s_{t}\left(l_{1}-l_{2}-\epsilon, l_{1}-l_{2}\right)  \tag{17}\\
& p_{24}(t)=\exp \left\{-\mu\left(l_{1}-l_{2}-\epsilon\right)-\frac{\mu^{2} t}{2}\right\} s s_{t}\left(\epsilon, l_{1}-l_{2}\right)  \tag{18}\\
& p_{31}(t)=\exp \left\{\mu\left(l_{1}-l_{2}-\epsilon\right)-\frac{\mu^{2} t}{2}\right\} s s_{t}\left(\epsilon, l_{1}-l_{2}\right)  \tag{19}\\
& p_{34}(t)=\exp \left\{-\mu \epsilon-\frac{\mu^{2} t}{2}\right\} s s_{t}\left(l_{1}-l_{2}-\epsilon, l_{1}-l_{2}\right)  \tag{20}\\
& p_{43}(t)=\frac{\epsilon}{\sqrt{2 \pi t^{3}}} \exp \left\{-\frac{(\epsilon-\mu t)^{2}}{2 t}\right\} \tag{21}
\end{align*}
$$

where

$$
s s_{t}(x, y)=\sum_{k=-\infty}^{\infty} \frac{(2 k+1) y-x}{\sqrt{2 \pi t^{3}}} \exp \left\{-\frac{((2 k+1) y-x)^{2}}{2 t}\right\}
$$

Also we know that

$$
\begin{equation*}
p_{23}(t)=p_{32}(t)=p_{14}(t)=p_{41}(t)=0 \tag{22}
\end{equation*}
$$

Clearly, all the arguments above apply to the standard Brownian motion, which is a special case of $W_{t}^{\mu}$ when $\mu=0$.

## 3 Results for the semi-Markov model

In $\S 2$ we have introduced the Markov process $\left(Z_{t}^{S}, V_{t}^{S}\right)$. Now we apply the same definition to the doubly perturbed Brownian motion $Y_{t}^{(\epsilon)}$; therefore we have $\left(Z_{t}^{Y}, V_{t}^{Y}\right)$, where $Z_{t}^{Y}$ is the current state of $Y_{t}^{(\epsilon)}$, taking value from state space $\{1,2,3,4\}$ and $V_{t}^{Y}$ is the time $Y_{t}^{(\epsilon)}$ has spent in current state. $V_{t}^{Y}$ is also a stochastic process. Now we consider a function of the form

$$
f\left(V_{t}^{Y}, Z_{t}^{Y}, t\right)=f_{Z_{t}^{Y}}\left(V_{t}^{Y}, t\right)
$$

where $f_{i}, i=1,2,3,4$ are functions from $\mathbb{R}^{2}$ to $\mathbb{R}$. The generator $\mathscr{A}$ is defined as an operator such that

$$
f\left(V_{t}^{Y}, Z_{t}^{Y}, t\right)-\int_{0}^{t} \mathscr{A} f\left(V_{s}^{Y}, Z_{s}^{Y}, s\right) \mathrm{d} s
$$

is a martingale (see [11], chapter 2). Therefore solving

$$
\mathscr{A} f=0
$$

subject to certain conditions will provide us with martingales of the form $f\left(V_{t}^{Y}, Z_{t}^{Y}, t\right)$ to which we can apply the optional stopping theorem to obtain the Laplace transform we are interested in. More precisely, we will have

$$
\left\{\begin{array}{l}
\mathscr{A} f_{1}(u, t)=\frac{\partial f_{1}(u, t)}{\partial t}+\frac{\partial f_{1}(u, t)}{\partial u}+\lambda_{12}(u)\left(f_{2}(0, t)-f_{1}(u, t)\right) \\
\mathscr{A} f_{2}(u, t)=\frac{\partial f_{2}(u, t)}{\partial t}+\frac{\partial f_{2}(u, t)}{\partial u}+\lambda_{21}(u)\left(f_{1}(0, t)-f_{2}(u, t)\right)+\lambda_{24}(u)\left(f_{4}(0, t)-f_{2}(u, t)\right) \\
\mathscr{A} f_{3}(u, t)=\frac{\partial f_{3}(u, t)}{\partial t}+\frac{\partial f_{3}(u, t)}{\partial u}+\lambda_{31}(u)\left(f_{1}(0, t)-f_{3}(u, t)\right)+\lambda_{34}(u)\left(f_{4}(0, t)-f_{3}(u, t)\right) \\
\mathscr{A} f_{4}(u, t)=\frac{\partial f_{4}(u, t)}{\partial t}+\frac{\partial f_{4}(u, t)}{\partial u}+\lambda_{43}(u)\left(f_{4}(0, t)-f_{3}(u, t)\right)
\end{array}\right.
$$

Assume $f_{i}$ has the form

$$
f_{i}(u, t)=e^{-\beta t} g_{i}(u) .
$$

By solving the equation $\mathscr{A} f=0$, i.e. $\left\{\begin{array}{l}\mathscr{A} f_{1}=0 \\ \mathscr{A} f_{2}=0 \\ \mathscr{A} f_{3}=0 \\ \mathscr{A} f_{4}=0\end{array}\right.$ we can get $\quad$ subject to $\left\{\begin{array}{l}g_{1}\left(d_{1}\right)=\alpha_{1} \\ g_{2}\left(d_{2}\right)=\alpha_{2} \\ g_{3}\left(d_{2}\right)=\alpha_{3} \\ g_{4}\left(d_{2}\right)=\alpha_{4}\end{array}\right.$ we can get

$$
\begin{align*}
g_{i}(u)= & \alpha_{i} \exp \left\{-\int_{u}^{d_{i}}\left(\beta+\sum_{j \neq i} \lambda_{i j}(v)\right) \mathrm{d} v\right\}  \tag{23}\\
& +\sum_{j \neq i} g_{j}(0) \int_{u}^{d_{i}} \lambda_{i j}(s) \exp \left\{-\int_{u}^{s}\left(\beta+\sum_{k \neq i} \lambda_{i k}(v)\right) \mathrm{d} v\right\} \mathrm{d} s .
\end{align*}
$$

In our case, we are only interested in the excursion inside the corridor. Hence, we set $d_{1}$ and $d_{4}$ to be $\infty$. Also $\lim _{d_{1} \rightarrow \infty} g_{1}\left(d_{1}\right)=\lim _{d_{4} \rightarrow \infty} g_{4}\left(d_{4}\right)=0$ gives $\alpha_{1}=\alpha_{4}=0$. Therefore, we have

$$
\begin{align*}
g_{2}(0) & =\alpha_{2} e^{-\beta d_{2}} \bar{P}_{2}\left(d_{2}\right)+g_{2}(0) \hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)+g_{3}(0) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)  \tag{24}\\
g_{3}(0) & =\alpha_{3} e^{-\beta d_{3}} \bar{P}_{3}\left(d_{3}\right)+g_{2}(0) \hat{P}_{12}(\beta) \tilde{P}_{31}(\beta)+g_{3}(0) \hat{P}_{43}(\beta) \tilde{P}_{34}(\beta) \tag{25}
\end{align*}
$$

Solving (24) and (25) gives

$$
\begin{align*}
g_{2}(0) & =\frac{\alpha_{2} e^{-\beta d_{2}} \bar{P}_{2}\left(d_{2}\right)\left(1-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)\right)+\alpha_{3} e^{-\beta d_{3}} \bar{P}_{3}\left(d_{3}\right) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)}{1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)+\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)-\hat{P}_{12}(\beta) \tilde{P}_{31}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)},  \tag{26}\\
g_{3}(0) & =\frac{\alpha_{3} e^{-\beta d_{3}} \bar{P}_{3}\left(d_{3}\right)\left(1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)\right)+\alpha_{2} e^{-\beta d_{2}} \bar{P}_{2}\left(d_{2}\right) \hat{P}_{12}(\beta) \tilde{P}_{31}(\beta)}{1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)+\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)-\hat{P}_{12}(\beta) \tilde{P}_{31}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)} .
\end{align*}
$$

where

$$
\begin{align*}
& \hat{P}_{i j}(\beta)=\int_{0}^{\infty} e^{-\beta s} p_{i j}(s) \mathrm{d} s  \tag{28}\\
& \tilde{P}_{i j}(\beta)=\int_{0}^{d_{i}} e^{-\beta s} p_{i j}(s) \mathrm{d} s \tag{29}
\end{align*}
$$

As a result, we have obtained the martingale

$$
\begin{equation*}
M_{t}=f\left(V_{t}^{Y}, t\right)=e^{-\beta t} g_{Z_{t}^{Y}}\left(V_{t}^{Y}\right), \quad i=1,2,3,4 \tag{30}
\end{equation*}
$$

We now can apply the optional stopping theorem to $M_{t}$ with the stopping time $\tau^{Y} \wedge t$, where $\tau^{Y}$ is the stopping time defined by (6):

$$
\begin{equation*}
E\left(M_{\tau^{Y} \wedge t}\right)=E\left(M_{0}\right) . \tag{31}
\end{equation*}
$$

The right hand side of (31) is

$$
E\left(M_{\tau^{Y} \wedge t}\right)=E\left(M_{\tau^{Y}} \mathbf{1}_{\left\{\tau^{Y}<t\right\}}\right)+E\left(M_{t} \mathbf{1}_{\left\{\tau^{Y}>t\right\}}\right) .
$$

Furthermore,

$$
\begin{aligned}
& E\left(M_{\tau^{Y}} \mathbf{1}_{\left\{\tau^{Y}<t\right\}}\right) \\
= & E\left(M_{\tau^{Y}} \mathbf{1}_{\left\{\tau_{2}^{Y}<\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{2}^{Y}<t\right\}}\right)+E\left(M_{\tau^{Y}} \mathbf{1}_{\left\{\tau_{2}^{Y}>\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{3}^{Y}<t\right\}}\right) \\
= & E\left(e^{-\beta \tau^{Y}} g_{2}\left(d_{2}\right) \mathbf{1}_{\left\{\tau_{2}^{Y}<\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{2}^{Y}<t\right\}}\right)+E\left(e^{-\beta \tau^{Y}} g_{3}\left(d_{3}\right) \mathbf{1}_{\left\{\tau_{2}^{Y}>\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{3}^{Y}<t\right\}}\right) \\
= & \alpha_{2} E\left(e^{-\beta \tau^{Y}} \mathbf{1}_{\left\{\tau_{2}^{Y}<\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{2}^{Y}<t\right\}}\right)+\alpha_{3} E\left(e^{-\beta \tau^{Y}} \mathbf{1}_{\left\{\tau_{2}^{Y}>\tau_{3}^{Y}\right\}} \mathbf{1}_{\left\{\tau_{3}^{Y}<t\right\}}\right) .
\end{aligned}
$$

We also have

$$
E\left(M_{t} \mathbf{1}_{\left\{\tau^{Y}>t\right\}}\right)=e^{-\beta t} E\left(g_{Z_{t}^{Y}}\left(V_{t}^{Y}\right) \mathbf{1}_{\left\{\tau^{Y}>t\right\}}\right)
$$

where $Z_{t}^{Y}$ can take values $1,2,3$ or 4 .
When $Z_{t}^{Y}=2$ or 3 , since $\tau^{Y}>t$, we have $0 \leq V_{t}^{Y}<d_{2} \wedge d_{3}$. According to the definition of $g_{i}(\mu)$ in (23), we have $g_{2}\left(V_{t}^{Y}\right)$ and $g_{3}\left(V_{t}^{Y}\right)$ are bounded.

When $Z_{t}^{Y}=1$ or 4 , since $\lim _{d_{1} \rightarrow \infty} g_{1}\left(d_{1}\right)=\lim _{d_{4} \rightarrow \infty} g_{4}\left(d_{4}\right)=0$ and looking at (23) with $d_{1}$ and $d_{4}$ replaced by $\infty$ we have that $g_{1}\left(V_{t}^{Y}\right)$ and $g_{4}\left(V_{t}^{Y}\right)$ are bounded.

Therefore

$$
\lim _{t \rightarrow \infty} E\left(M_{t} \mathbf{1}_{\left\{\tau^{Y}>t\right\}}\right)=0
$$

The left hand side of (31) gives

$$
\lim _{t \rightarrow \infty} E\left(M_{0}\right)=E\left(M_{0}\right)=\left\{\begin{array}{ll}
g_{2}(0), & Y_{0}^{(\epsilon)}=l_{1}+\epsilon \\
g_{3}(0), & Y_{0}^{(\epsilon)}=l_{2}-\epsilon
\end{array} .\right.
$$

By taking $\alpha_{2}=\alpha_{3}=1$ and $d_{2}=d_{3}=d$, we will have when $Y_{0}^{(\epsilon)}=l_{1}+\epsilon$

$$
\begin{align*}
& E\left(e^{-\beta \tau^{Y}}\right)  \tag{32}\\
= & \frac{e^{-\beta d} \bar{P}_{2}(d)\left(1-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)\right)+e^{-\beta d} \bar{P}_{3}(d) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)}{1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)+\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)-\hat{P}_{12}(\beta) \tilde{P}_{31}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)},
\end{align*}
$$

when $Y_{0}^{(\epsilon)}=l_{2}-\epsilon$

$$
\begin{align*}
& E\left(e^{-\beta \tau^{Y}}\right)  \tag{33}\\
= & \frac{e^{-\beta d} \bar{P}_{2}(d) \hat{P}_{12}(\beta) \tilde{P}_{31}(\beta)+e^{-\beta d} \bar{P}_{3}(d)\left(1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)\right)}{1-\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta)-\hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)+\hat{P}_{12}(\beta) \tilde{P}_{21}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{34}(\beta)-\hat{P}_{12}(\beta) \tilde{P}_{31}(\beta) \hat{P}_{43}(\beta) \tilde{P}_{24}(\beta)} .
\end{align*}
$$

## 4 Main Results

In $\S 2$ we have stated that the main difficulty with the Brownian Motion is that its origin point is regular, i.e. the probability that $W_{t}^{\mu}$ will return to the origin at arbitrarily small time is 1 . We have therefore introduced the new processes $Y_{t}^{(\epsilon)}$ and $\left(Z_{t}^{Y}, V_{t}^{Y}\right)$ with transition densities for $Z_{t}^{Y}$ defined in (16) to (22).

Theorem 1 For a Brownian Motion $W_{t}^{\mu}, \tau^{W^{\mu}}$ defined as in (6) with $S_{t}=W_{t}^{\mu}$, we have following Laplace transforms:
when $W_{0}^{\mu}=l_{1}$,

$$
\begin{equation*}
E\left(e^{-\beta \tau^{W^{\mu}}}\right)=e^{-\beta d} \frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)} \tag{34}
\end{equation*}
$$

when $W_{0}^{\mu}=l_{2}$,

$$
\begin{equation*}
E\left(e^{-\beta \tau^{W^{\mu}}}\right)=e^{-\beta d} \frac{e^{\mu l} F_{1}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{2}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)} ; \tag{35}
\end{equation*}
$$

where

$$
\begin{align*}
& l=l_{1}-l_{2} ;  \tag{36}\\
& F_{1}(x)= \sqrt{\frac{2}{\pi d}} \sum_{k=-\infty}^{\infty} e^{-2|x| l \mid k}\left\{\exp \left\{-\frac{1}{2}\left(\frac{2 l k}{\sqrt{d}}-|x| \sqrt{d}\right)^{2}\right\}\right.  \tag{37}\\
&\left.-e^{-(|x|+x) l} \exp \left\{-\frac{1}{2}\left(\frac{l(2 k+1)}{\sqrt{d}}-|x| \sqrt{d}\right)^{2}\right\}\right\} \\
&+2|x| \sum_{k=-\infty}^{\infty} e^{-2|x| l k}\left\{e^{-(|x|+x) l} \mathscr{N}\left(\frac{l(2 k+1)}{\sqrt{d}}-|x| \sqrt{d}\right)-\mathscr{N}\left(\frac{2 l k}{\sqrt{d}}-|x| \sqrt{d}\right)\right\} \\
& F_{2}(x)= \sqrt{\frac{2}{\pi d}} \sum_{k=-\infty}^{\infty} e^{-2|x| l k}\left\{\exp \left\{-\frac{1}{2}\left(\frac{2 l k}{\sqrt{d}}-|x| \sqrt{d}\right)^{2}\right\}\right.  \tag{38}\\
&\left.-e^{-(|x|-x) l} \exp \left\{-\frac{1}{2}\left(\frac{l(2 k+1)}{\sqrt{d}}-|x| \sqrt{d}\right)^{2}\right\}\right\} \\
&+2|x| \sum_{k=-\infty}^{\infty} e^{-2|x| l k}\left\{e^{-(|x|-x) l} \mathscr{N}\left(\frac{l(2 k+1)}{\sqrt{d}}-|x| \sqrt{d}\right)-\mathscr{N}\left(\frac{2 l k}{\sqrt{d}}-|x| \sqrt{d}\right)\right\} \\
& G_{1}(x)= \frac{-2 \sqrt{2 x}}{1-e^{-2 l \sqrt{2 x}}}+2 \sqrt{2 x} \sum_{k=-\infty}^{\infty} e^{-2 l \sqrt{2 x} k} \mathscr{N}\left(\frac{2 l k}{\sqrt{d}}-\sqrt{2 x d}\right)  \tag{39}\\
&-\sqrt{\frac{2}{\pi d}} \sum_{k=-\infty}^{\infty} e^{-2 l \sqrt{2 x} k} \exp \left\{-\frac{1}{2}\left(\frac{2 l k}{\sqrt{d}}-\sqrt{2 x d}\right)^{2}\right\} \\
& G_{2}(x)= \frac{2 \sqrt{2 x} e^{-l \sqrt{2 x}}}{1-e^{-2 l \sqrt{2 x}}}-2 \sqrt{2 x} \sum_{k=-\infty}^{\infty} e^{-l \sqrt{2 x}(2 k+1)} \mathscr{N}\left(\frac{l(2 k+1)}{\sqrt{d}}-\sqrt{2 x d}\right) \\
&+\sqrt{\frac{2}{\pi d}} \sum_{k=-\infty}^{\infty} e^{-l \sqrt{2 x}(2 k+1)} \exp \left\{-\frac{1}{2}\left(\frac{l(2 k+1)}{\sqrt{d}}-\sqrt{2 x d}\right)^{2}\right\} \cdot(40) \tag{40}
\end{align*}
$$

Proof: We apply the transition densities in (16) to (22) to the results in (32) and (33) and taking the limit $\epsilon \rightarrow 0$. According to the definition of $Y^{(\epsilon)}$, we know that

$$
Y_{t}^{(\epsilon)} \xrightarrow{\text { a.s }} W_{t}^{\mu}, \quad \text { for all } t .
$$

As we saw in [9] when $Y_{t}^{(\epsilon)} \xrightarrow{\text { a.s }} W_{t}^{\mu}$, for all $t$, by taking the limit $\epsilon \rightarrow 0$, the quantities defined based on $Y_{t}^{(\epsilon)}$ converge to those based on Brownian motion with drift. Therefore we will get the results shown by (34) and (35).

Corollary 1.1 For a standard Brownian Motion $(\mu=0)$, we have for both cases (i.e. when $W_{0}=l_{1}$ and when $W_{0}=l_{2}$ )

$$
\begin{equation*}
E\left(e^{-\beta \tau^{W}}\right)=e^{-\beta d} \frac{h(0)}{h(\beta)} ; \tag{41}
\end{equation*}
$$

where

$$
\begin{align*}
h(\beta)= & \sqrt{\frac{2}{\pi d}} \sum_{k=-\infty}^{\infty} e^{-2 l \sqrt{2 \beta} k}\left\{e^{-l \sqrt{2 \beta}} \exp \left\{-\frac{1}{2}\left(\frac{l(2 k+1)}{\sqrt{d}}-\sqrt{2 \beta d}\right)^{2}\right\}\right.  \tag{42}\\
& \left.-\exp \left\{-\frac{1}{2}\left(\frac{2 l k}{\sqrt{d}}-\sqrt{2 \beta d}\right)^{2}\right\}\right\}-\frac{2 \sqrt{2 \beta}}{1+e^{-l \sqrt{2 \beta}}} \\
& +2 \sqrt{2 \beta} \sum_{k=-\infty}^{\infty} e^{-2 l \sqrt{2 \beta} k}\left\{\mathscr{N}\left(\frac{2 l k}{\sqrt{d}}-\sqrt{2 \beta d}\right)-e^{-l \sqrt{2 \beta}} \mathscr{N}\left(\frac{l(2 k+1)}{\sqrt{d}}-\sqrt{2 \beta d}\right)\right\}
\end{align*}
$$

We are also interested in the cases when a Brownian Motion starts from the point other than $l_{1}$ and $l_{2}$. The results are shown in the following corollary.

Corollary 1.2 For a Brownian Motion $W_{t}^{\mu}, \tau^{W^{\mu}}$ defined as in (6) with $S_{t}=$ $W_{t}^{\mu}$, we have the following Laplace transforms:
when $W_{0}^{\mu}=x_{0}, x_{0} \geq l_{1}$,

$$
\begin{align*}
E\left(e^{-\beta \tau^{W^{\mu}}}\right)= & \exp \left\{-\left(\mu+\sqrt{2 \beta+\mu^{2}}\right)\left(x_{0}-l_{1}\right)-\beta d\right\}  \tag{43}\\
& \frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)}
\end{align*}
$$

when $W_{0}^{\mu}=x_{0}, x_{0} \leq l_{2}$,

$$
\begin{align*}
E\left(e^{-\beta \tau^{W^{\mu}}}\right)= & \exp \left\{\left(\mu-\sqrt{2 \beta+\mu^{2}}\right)\left(l_{2}-x_{0}\right)-\beta d\right\}  \tag{44}\\
& \frac{e^{\mu l} F_{1}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{2}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)}
\end{align*}
$$

when $W_{0}^{\mu}=x_{0}, l_{2}<x_{0}<l_{1}$,

$$
\begin{align*}
& E\left(e^{-\beta \tau^{W^{\mu}}}\right)=e^{\mu\left(l_{2}-x_{0}\right)-\beta d} \sum_{k=-\infty}^{\infty}\left\{e^{-|\mu|\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}+\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right.  \tag{45}\\
& \left.-e^{|\mu|\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}-\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right\} \\
& +e^{\mu\left(l_{1}-x_{0}\right)-\beta d} \sum_{k=-\infty}^{\infty}\left\{e^{-|\mu|\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}+\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right. \\
& \left.-e^{|\mu|\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}-\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right\}+e^{-\beta d} \\
& -\frac{e^{-|\mu| l-\beta d}\left\{e^{\mu\left(l_{2}-x_{0}\right)}\left(e^{|\mu|\left(l_{1}-x_{0}\right)}-e^{-|\mu|\left(l_{1}-x_{0}\right)}\right)+e^{\mu\left(l_{1}-x_{0}\right)}\left(e^{|\mu|\left(x_{0}-l_{2}\right)}-e^{-|\mu|\left(x_{0}-l_{2}\right)}\right)\right\}}{1-e^{-2|\mu| l}} \\
& +\left[\frac{e^{-\sqrt{2 \beta+\mu^{2}} l} e^{\mu\left(l_{2}-x_{0}\right)}\left(e^{\sqrt{2 \beta+\mu^{2}}\left(l_{1}-x_{0}\right)}-e^{-\sqrt{2 \beta+\mu^{2}}\left(l_{1}-x_{0}\right)}\right)}{1-e^{-2 \sqrt{2 \beta+\mu^{2}} l}}\right. \\
& +e^{\mu\left(l_{2}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{\sqrt{2 \beta+\mu^{2}}\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}-\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right. \\
& \left.\left.-e^{-\sqrt{2 \beta+\mu^{2}}\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}+\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right\}\right] \\
& \frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)} \\
& +\left[\frac{e^{-\sqrt{2 \beta+\mu^{2}} l} e^{\mu\left(l_{1}-x_{0}\right)}\left(e^{\sqrt{2 \beta+\mu^{2}}\left(x_{0}-l_{2}\right)}-e^{-\sqrt{2 \beta+\mu^{2}}\left(x_{0}-l_{2}\right)}\right)}{1-e^{-2 \sqrt{2 \beta+\mu^{2}} l}}\right. \\
& +e^{\mu\left(l_{1}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{\sqrt{2 \beta+\mu^{2}}\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}-\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right. \\
& \left.\left.-e^{-\sqrt{2 \beta+\mu^{2}}\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}+\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right\}\right] \\
& \frac{e^{\mu l} F_{1}(\mu) G_{2}\left(\beta+\frac{\mu^{2}}{2}\right)-F_{2}(\mu) G_{1}\left(\beta+\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\beta+\frac{\mu^{2}}{2}\right)} .
\end{align*}
$$

$E\left(e^{-\beta \tau^{\widetilde{W}^{\mu}}}\right)$ has been calculate in Theorem 1 (34). According to [4], we have

$$
E\left(e^{-\beta T}\right)=\exp \left\{-\left(\mu+\sqrt{2 \beta+\mu^{2}}\right)\left(x_{0}-l_{1}\right)\right\}
$$

For the case when $x_{0} \leq l_{2}$, we can apply the same argument.
When $l_{2}<x_{0}<l_{1}$, by definition, we have $\tau^{W^{\mu}}=d$, if $T \geq d ; \tau^{W^{\mu}}=$ $T+\tau \widetilde{W}^{\mu}$, if $T<d$, and $W_{T}^{\mu}=l_{1}$ where $\widetilde{W}^{\mu}$ here stands for a Brownian motion with drift started from $l_{1} ; \tau^{W^{\mu}}=T+\tau \underline{\underline{W}}^{\mu}$, if $T<d$, and $W_{T}^{\mu}=l_{2}$ where $\underline{W}^{\mu}$ here stands for a Brownian motion with drift started from $l_{2}$. As a result

$$
\begin{aligned}
& E\left(e^{-\beta \tau^{W^{\mu}}}\right) \\
= & E\left(e^{-\beta \tau^{W^{\mu}}} \mathbf{1}_{\{T \geq d\}}\right)+E\left(e^{-\beta \tau^{W^{\mu}}} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{1}\right\}}\right)+E\left(e^{-\beta \tau^{W^{\mu}}} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{2}\right\}}\right) \\
= & e^{-\beta d} P(T \geq d)+E\left(e^{-\beta T} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{1}\right\}}\right) E\left(e^{-\beta \tau^{\widetilde{W}}}\right) \\
& +E\left(e^{-\beta T} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{2}\right\}}\right) E\left(e^{-\beta \tau^{W^{\mu}}}\right)
\end{aligned}
$$

$E\left(e^{-\beta \tau^{\widetilde{W}^{\mu}}}\right)$ and $E\left(e^{-\beta \tau \underline{W}^{\mu}}\right)$ have been calculated in Theorem 1 (see (34) and (35)). The density for $T$ is given in [4] as

$$
p_{x_{0}}(t)=e^{\mu\left(l_{2}-x_{0}\right)-\frac{\mu^{2} t}{2}} s s_{t}\left(l_{1}-x_{0}, l\right)+e^{\mu\left(l_{1}-x_{0}\right)-\frac{\mu^{2} t}{2}} s s_{t}\left(x_{0}-l_{2}, l\right) .
$$

We can therefore calculate

$$
\begin{aligned}
& P(T \geq d) \\
= & 1-\frac{e^{-|\mu| l}\left\{e^{\mu\left(l_{2}-x_{0}\right)}\left(e^{|\mu|\left(l_{1}-x_{0}\right)}-e^{-|\mu|\left(l_{1}-x_{0}\right)}\right)+e^{\mu\left(l_{1}-x_{0}\right)}\left(e^{|\mu|\left(x_{0}-l_{2}\right)}-e^{-|\mu|\left(x_{0}-l_{2}\right)}\right)\right\}}{1-e^{-2|\mu| l}} \\
& +e^{\mu\left(l_{2}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{-|\mu|\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}+\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right. \\
& \left.-e^{|\mu|\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}-\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right\} \\
& +e^{\mu\left(l_{1}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{-|\mu|\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}+\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right. \\
& \left.-e^{|\mu|\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-|\mu| \sqrt{d}-\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right\} .
\end{aligned}
$$

$$
\begin{aligned}
& E\left(e^{-\beta T} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{1}\right\}}\right) \\
= & \frac{e^{-\sqrt{2 \beta+\mu^{2}}} e^{\mu\left(l_{2}-x_{0}\right)}\left(e^{\sqrt{2 \beta+\mu^{2}}\left(l_{1}-x_{0}\right)}-e^{-\sqrt{2 \beta+\mu^{2}}\left(l_{1}-x_{0}\right)}\right)}{1-e^{-2 \sqrt{2 \beta+\mu^{2}} l}} \\
& +e^{\mu\left(l_{2}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{\sqrt{2 \beta+\mu^{2}}\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}-\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right. \\
& \left.-e^{-\sqrt{2 \beta+\mu^{2}}\left(2 k l+x_{0}-l_{2}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}+\frac{2 k l+x_{0}-l_{2}}{\sqrt{d}}\right)\right\} \\
= & \frac{E\left(e^{-\beta T} \mathbf{1}_{\{T<d\}} \mathbf{1}_{\left\{W_{T}^{\mu}=l_{2}\right\}}^{\mu}\right)}{1-e^{-2 \sqrt{2 \beta+\mu^{2}} l}} \\
& +e^{\mu\left(l_{1}-x_{0}\right)} \sum_{k=-\infty}^{\infty}\left\{e^{\sqrt{2 \beta+\mu^{2}}\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}-\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right. \\
& \left.-e^{-\sqrt{2 \beta+\mu^{2}}\left(2 k l-x_{0}+l_{1}\right)} \mathscr{N}\left(-\sqrt{\left(2 \beta+\mu^{2}\right) d}+\frac{2 k l-x_{0}+l_{1}}{\sqrt{d}}\right)\right\} .
\end{aligned}
$$

We therefore get the result in (45).
Notice that for a Brownian motion with drift, it is possible that $\tau^{W^{\mu}}$ will never be achieved. Take the case when $\mu>0$ and $x_{0}>l_{1}$ as an example. We obtain the following result by taking $\beta=0$ in (43).

Corollary 1.3 For a Brownian motion with positive drift, $W^{\mu}$ with $\mu>0$ and $x_{0}>l_{1}$ we have that,
$P\left(\tau^{W^{\mu}}<\infty\right)=\exp \left\{-2 \mu\left(x_{0}-l_{1}\right)\right\} \frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\frac{\mu^{2}}{2}\right)}$.
Remark 1: As a result, for a Brownian motion with positive drift and $x_{0}>l_{1}$, with probability

$$
1-\exp \left\{-2 \mu\left(x_{0}-l_{1}\right)\right\} \frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\frac{\mu^{2}}{2}\right)}
$$

that it will never achieved a excursion in the corridor $\left(l_{2}, l_{1}\right)$ with length equal or greater than $d$.

Remark 2: For a Brownian motion with negative drift and $x_{0}>l_{1}$, taking $\beta=0$ in (43) gives that with probability

$$
1-\frac{e^{-\mu l} F_{2}(\mu) G_{2}\left(\frac{\mu^{2}}{2}\right)-F_{1}(\mu) G_{1}\left(\frac{\mu^{2}}{2}\right)}{G_{1}^{2}\left(\frac{\mu^{2}}{2}\right)-G_{2}^{2}\left(\frac{\mu^{2}}{2}\right)}
$$

that it will never achieved a excursion in the corridor $\left(l_{2}, l_{1}\right)$ with length equal or greater than $d$.

Remark 3: For a standard Brownian motion, we can carry out a similar calculation to (41), from which we can easily that the result that

$$
P\left(\tau^{W}<\infty\right)=1
$$

We will now extent Corollary 1.2 to obtain the joint distribution of $W_{t}$ and $\tau^{W}$ at an exponential time. This is an application of (43), (44) and Girsanov's theorem.

Theorem 2 For a standard Brownian Motion $W_{t}$ with $W_{0}=x_{0}$ and $\tau^{W}$ defined as in (6) with $S_{t}=W_{t}$, we have the following result:

For the case $x_{0} \geq l_{1}$ and $x \geq l_{1}$,

$$
\begin{align*}
& P\left(W_{\tilde{T}} \in \mathrm{~d} x, \tau^{W}<\tilde{T}\right)  \tag{47}\\
= & \gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\} \frac{G_{2}(\gamma)\left(u_{1}\left(x-l_{1}\right)-u_{2}\left(x-l_{2}\right)\right)-G_{1}(\gamma)\left(u_{1}\left(x-l_{2}\right)-u_{2}\left(x-l_{1}\right)\right)}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}
\end{align*}
$$

for the case $x_{0} \geq l_{1}$ and $l_{2}<x<l_{1}$,

$$
\begin{align*}
& P\left(W_{\tilde{T}} \in \mathrm{~d} x, \tau^{W}<\tilde{T}\right)  \tag{48}\\
= & \gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\} \frac{G_{2}(\gamma)\left(u_{3}\left(x-l_{1}\right)-u_{2}\left(x-l_{2}\right)\right)-G_{1}(\gamma)\left(u_{1}\left(x-l_{2}\right)-u_{4}\left(x-l_{1}\right)\right)}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}
\end{align*}
$$

for the case $x_{0} \geq l_{1}$ and $x \leq l_{2}$,

$$
\begin{align*}
& P\left(W_{\tilde{T}} \in \mathrm{~d} x, \tau^{W}<\tilde{T}\right)  \tag{49}\\
= & \gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\} \frac{G_{2}(\gamma)\left(u_{3}\left(x-l_{1}\right)-u_{4}\left(x-l_{2}\right)\right)-G_{1}(\gamma)\left(u_{3}\left(x-l_{2}\right)-u_{4}\left(x-l_{1}\right)\right)}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}
\end{align*}
$$

for the case $x \leq l_{2}$ and $x \geq l_{1}$,

$$
\begin{align*}
& P\left(W_{\tilde{T}} \in \mathrm{~d} x, \tau^{W}<\tilde{T}\right)  \tag{50}\\
= & \gamma \exp \left\{-\sqrt{2 \gamma}\left(l_{2}-x_{0}\right)\right\} \frac{G_{2}(\gamma)\left(u_{1}\left(x-l_{2}\right)-u_{2}\left(x-l_{1}\right)\right)-G_{1}(\gamma)\left(u_{1}\left(x-l_{1}\right)-u_{2}\left(x-l_{2}\right)\right)}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}},
\end{align*}
$$

for the case $x \leq l_{2}$ and $l_{2}<x<l_{1}$,

$$
\begin{align*}

Proof: see appendix.

## 5 Pricing Parisian Corridor Options

We want to price a Parisian corridor in-call option with the current price of its underlying asset to be $x, x>L_{1}$, the owner of which will obtain the right to exercise it when the length of the excursion inside the corridor formed by the barriers $L_{1}$ and $L_{2}\left(L_{1}>L_{2}\right)$ reaches $d$ before $T$. Its price formula is given by

$$
P C_{\text {in-call }}=e^{-r T} E_{Q}\left(\left(S_{T}-K\right)^{+} \mathbf{1}_{\left\{\tau^{S}<T\right\}}\right),
$$

where $S$ is the underlying stock price, $Q$ denotes the risk neutral measure, $\tau^{S}$ is defined with the respect to $L_{1}$ and $L_{2}$. We assume $S$ is a geometric Brownian motion:

$$
\mathrm{d} S_{t}=r S_{t} \mathrm{~d} t+\sigma S_{t} \mathrm{~d} W_{t}, \quad S_{0}=x
$$

where $x>L_{1}, r$ is the risk free rate, $W_{t}$ with $W_{0}=0$ is a standard Brownian motion under $Q$. Set

$$
\begin{gathered}
m=\frac{1}{\sigma}\left(r-\frac{1}{2} \sigma^{2}\right), \quad b=\frac{1}{\sigma} \ln \left(\frac{K}{x}\right), \quad B_{t}=m t+W_{t}, \\
l_{1}=\frac{1}{\sigma} \ln \left(\frac{L_{1}}{x}\right), \quad l_{2}=\frac{1}{\sigma} \ln \left(\frac{L_{2}}{x}\right) .
\end{gathered}
$$

We have

$$
S_{t}=x \exp \left\{\left(r-\frac{1}{2} \sigma^{2}\right) t+\sigma W_{t}\right\}=x \exp \left\{\sigma\left(m t+W_{t}\right)\right\}=x e^{\sigma B_{t}}
$$

By applying Girsanov's Theorem, we have

$$
P C_{i n-\text { call }}=e^{-\left(r+\frac{1}{2} m^{2}\right) T} E_{P}\left[\left(x e^{\sigma B_{T}}-K\right)^{+} e^{m B_{T}} \mathbf{1}_{\left\{\tau^{B}<T\right\}}\right]
$$

where $P$ is a new measure, under which $B_{t}$ is a standard Brownian motion with $B_{0}=0$, and $\tau^{B}$ is the stopping time defined with respect to barrier $l_{1}, l_{2}$. And we define

$$
P C_{i n-\text { call }}^{*}=e^{\left(r+\frac{1}{2} m^{2}\right) T} P C_{i n-\text { call }}
$$

We are going to show that we can obtain the Laplace transform of $P C_{i n-c a l l}^{*}$ w.r.t $T$, denoted by $\mathscr{L}_{T}$.

Firstly, assuming $\tilde{T}$ is a random variable with an exponential distribution of parameter $\gamma$ that is independent of $W_{t}$, we have

$$
\begin{aligned}
& E_{P}\left[\left(x e^{\sigma B_{\tilde{T}}}-K\right)^{+} e^{m B_{\tilde{T}}} \mathbf{1}_{\left\{\tau^{B}<\tilde{T}\right\}}\right] \\
= & \int_{b}^{\infty}\left(x e^{\sigma y}-K\right) e^{m y} P\left(B_{\tilde{T}} \in \mathrm{~d} y, \tau^{B}<\tilde{T}\right) \\
= & \int_{0}^{\infty} \gamma e^{-\gamma T} \int_{b}^{\infty}\left(x e^{\sigma y}-K\right) e^{m y} P\left(B_{T} \in \mathrm{~d} y, \tau^{B}<T\right) \mathrm{d} T \\
= & \gamma \int_{0}^{\infty} e^{-\gamma T} E_{P}\left[\left(x e^{\sigma B_{T}}-K\right)^{+} e^{m B_{T}} \mathbf{1}_{\left\{\tau^{B}<T\right\}}\right] \mathrm{d} T \\
= & \gamma \mathscr{L}_{T}
\end{aligned}
$$

Hence we have

$$
\mathscr{L}_{T}=\frac{1}{\gamma} \int_{b}^{\infty}\left(x e^{\sigma y}-K\right) e^{m y} P\left(B_{\tilde{T}} \in \mathrm{~d} y, \tau^{B}<\tilde{T}\right) .
$$

By using the results in Theorem 3, this Laplace transform can be calculated explicitly.

When $b \geq l_{1}$, i.e. $K \geq L_{1}$, we have

$$
\begin{equation*}
\mathscr{L}_{T}=\frac{x}{\gamma} F_{1}(\sigma+m)-\frac{K}{\gamma} F_{1}(m), \tag{59}
\end{equation*}
$$

when $l_{2}<b<l_{1}$, i.e. $L_{2}<K<L_{1}$, we have

$$
\begin{equation*}
\mathscr{L}_{T}=\frac{x}{\gamma} F_{2}(\sigma+m)-\frac{K}{\gamma} F_{2}(m), \tag{60}
\end{equation*}
$$

when $b \leq l_{2}$, i.e. $K \leq L_{2}$, we have

$$
\begin{equation*}
\mathscr{L}_{T}=\frac{x}{\gamma} F_{3}(\sigma+m)-\frac{K}{\gamma} F_{3}(m), \tag{61}
\end{equation*}
$$

where

$$
\begin{align*}
F_{1}(x)= & \frac{\gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\}}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}\left[G_{2}(\gamma)\left\{q_{1}\left(x, b, l_{1}\right)-q_{2}\left(x, b, l_{2}\right)\right\}\right. \\
& \left.-G_{1}(\gamma)\left\{q_{1}\left(x, b, l_{2}\right)-q_{2}\left(x, b, l_{1}\right)\right\}\right], \\
F_{2}(x)= & \frac{\gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\}}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}\left[G_{2}(\gamma)\left\{q_{1}\left(x, l_{1}, l_{1}\right)-q_{2}\left(x, b, l_{2}\right)+q_{3}\left(x, l_{1}, l_{1}\right)-q_{3}\left(x, b, l_{1}\right)\right\}\right. \\
& \left.-G_{1}(\gamma)\left\{q_{1}\left(x, b, l_{2}\right)-q_{2}\left(x, l_{1}, l_{1}\right)-q_{4}\left(x, l_{1}, l_{1}\right)+q_{4}\left(x, b, l_{1}\right)\right\}\right],  \tag{63}\\
F_{3}(x)= & \frac{\gamma \exp \left\{-\sqrt{2 \gamma}\left(x_{0}-l_{1}\right)\right\}}{G_{1}(\gamma)^{2}-G_{2}(\gamma)^{2}}\left[G _ { 2 } ( \gamma ) \left\{q_{1}\left(x, l_{1}, l_{1}\right)-q_{2}\left(x, l_{2}, l_{2}\right)+q_{3}\left(x, l_{1}, l_{1}\right)-q_{3}\left(x, b, l_{1}\right)\right.\right. \\
& \left.+q_{4}\left(x, b, l_{2}\right)-q_{4}\left(x, l_{2}, l_{2}\right)\right\}-G_{1}(\gamma)\left\{q_{1}\left(x, l_{2}, l_{2}\right)-q_{2}\left(x, l_{1}, l_{1}\right)+q_{3}\left(x, l_{2}, l_{2}\right)\right.
\end{aligned} \quad \begin{aligned}
&\left.\left.-q_{3}\left(x, b, l_{2}\right)-q_{4}\left(x, l_{1}, l_{1}\right)+q_{4}\left(x, b, l_{1}\right)\right\}\right], \\
& q_{1}(x, y, z)=\frac{e^{(x-\sqrt{2 \gamma}) y+\sqrt{2 \gamma} z}}{\sqrt{2 \gamma}-x} a_{1}(-\sqrt{2 \gamma}),  \tag{64}\\
& q_{2}(x, y, z)=\frac{e^{(x-\sqrt{2 \gamma}) y+\sqrt{2 \gamma} z}}{\sqrt{2 \gamma}-x} a_{2}(-\sqrt{2 \gamma}), \tag{65}
\end{align*}
$$

$$
\begin{align*}
& q_{3}(x, y, z)=2 \sum_{k=-\infty}^{\infty} \frac{\exp \{-\sqrt{2 \gamma}((2 k+1) l-z)\}}{x-\sqrt{2 \gamma}}\left[e^{(x-\sqrt{2 \gamma}) y} \mathscr{N}\left(\frac{y-z+(2 k+1) l-\sqrt{2 \gamma} d}{\sqrt{d}}\right)\right. \\
& -\exp \left\{(x-\sqrt{2 \gamma})(z-(2 k+1) l+\sqrt{2 \gamma} d)+\frac{(x-\sqrt{2 \gamma})^{2} d}{2}\right\} \\
& \left.\mathscr{N}\left(\frac{y-z+(2 k+1) l-x d}{\sqrt{d}}\right)\right] \\
& +2 \sum_{k=-\infty}^{\infty} \frac{\exp \{\sqrt{2 \gamma}((2 k+1) l-z)\}}{x+\sqrt{2 \gamma}}\left[e^{(x+\sqrt{2 \gamma}) y} \mathscr{N}\left(\frac{y-z+(2 k+1) l+\sqrt{2 \gamma} d}{\sqrt{d}}\right)\right. \\
& -\exp \left\{(x+\sqrt{2 \gamma})(z-(2 k+1) l-\sqrt{2 \gamma} d)+\frac{(x+\sqrt{2 \gamma})^{2} d}{2}\right\} \\
& \left.\mathscr{N}\left(\frac{y-z+(2 k+1) l-x d}{\sqrt{d}}\right)\right]-\frac{e^{(\sqrt{2 \gamma}+x) y-\sqrt{2 \gamma} z}}{x+\sqrt{2 \gamma}} a_{1}(\sqrt{2 \gamma}),  \tag{67}\\
& q_{4}(x, y, z)=2 \sum_{k=-\infty}^{\infty} \frac{\exp \{-\sqrt{2 \gamma}(2 k l-z)\}}{x-\sqrt{2 \gamma}}\left[e^{(x-\sqrt{2 \gamma}) y} \mathscr{N}\left(\frac{y-z+2 k l-\sqrt{2 \gamma} d}{\sqrt{d}}\right)\right. \\
& \left.-\exp \left\{(x-\sqrt{2 \gamma})(z-2 k l+\sqrt{2 \gamma} d)+\frac{(x-\sqrt{2 \gamma})^{2} d}{2}\right\} \mathscr{N}\left(\frac{y-z+2 k l-x d}{\sqrt{d}}\right)\right] \\
& +2 \sum_{k=-\infty}^{\infty} \frac{\exp \{\sqrt{2 \gamma}(2 k l-z)\}}{x+\sqrt{2 \gamma}}\left[e^{(x+\sqrt{2 \gamma}) y} \mathscr{N}\left(\frac{y-z+(2 k+1) l+\sqrt{2 \gamma} d}{\sqrt{d}}\right)\right. \\
& \left.-\exp \left\{(x+\sqrt{2 \gamma})(z-2 k l-\sqrt{2 \gamma} d)+\frac{(x+\sqrt{2 \gamma})^{2} d}{2}\right\} \mathscr{N}\left(\frac{y-z+2 k l-x d}{\sqrt{d}}\right)\right] \\
& -\frac{e^{(\sqrt{2 \gamma}+x) y-\sqrt{2 \gamma} z}}{x+\sqrt{2 \gamma}} a_{2}(\sqrt{2 \gamma}) . \tag{68}
\end{align*}
$$

Remark: The price can be calculated by numerical inversion of the Laplace transform.

So far, we have shown how to obtain the Laplace transform of

$$
P C_{i n-\text { call }}^{*}=e^{\left(r+\frac{1}{2} m^{2}\right) T} P_{\text {in-call }}
$$

For

$$
P C_{\text {out-call }}=e^{-r T} E_{Q}\left(\left(S_{T}-K\right)^{+} \mathbf{1}_{\left\{\tau^{S}>T\right\}}\right),
$$

we can get the result from the relationship that

$$
P C_{\text {out-call }}=e^{-r T} E_{Q}\left\{\left(S_{T}-K\right)^{+}\right\}-P C_{\text {in-call }} .
$$

## 6 Appendix: Proof of Theorem 2

Let $T$ be the final time. According to the definition of $\Psi(x)$, we have

$$
\Psi(x)=2 \sqrt{\pi} x \mathscr{N}(\sqrt{2} x)-\sqrt{\pi} x+e^{-x^{2}}=\sqrt{\pi} x-\sqrt{\pi} x \operatorname{Erfc}(x)+e^{-x^{2}}
$$

It is not difficult to show that

$$
E\left(e^{-\beta \tau^{W^{\mu}}}\right)=E\left(\int_{0}^{\infty} \beta e^{-\beta T} \mathbf{1}_{\left\{\tau^{W^{\mu}}<T\right\}} \mathrm{d} T\right)
$$

By Girsanov's theorem, this is equal to

$$
\int_{0}^{\infty} \beta e^{-\left(\beta+\frac{1}{2} \mu^{2}\right) T-\mu x_{0}} E\left(e^{\mu W_{T}} \mathbf{1}_{\left\{\tau \tau^{W}<T\right\}}\right) \mathrm{d} T .
$$

Setting $\gamma=\beta+\frac{1}{2} \mu^{2}$ gives

$$
\begin{aligned}
E\left(e^{-\beta \tau^{W^{\mu}}}\right) & \left.=\int_{0}^{\infty}\left(\gamma-\frac{1}{2} \mu^{2}\right) e^{-\gamma T-\mu x_{0}} E\left(e^{\mu W_{T}} \mathbf{1}_{\{\tau W}<T\right\}\right) \mathrm{d} T \\
& =\frac{\gamma-\frac{1}{2} \mu^{2}}{\gamma} e^{-\mu x_{0}} E\left(e^{\mu W_{\tilde{T}}} \mathbf{1}_{\left\{\tau^{W}<\tilde{T}\right\}}\right)
\end{aligned}
$$

where $\tilde{T}$ is a random variable with an exponential distribution of parameter $\gamma$ that is independent of $W_{t}$. Therefore we have

$$
\left.E\left(e^{\mu W_{\tilde{T}}} \mathbf{1}_{\{\tau W}<\tilde{T}\right\}\right)=\frac{\gamma e^{\mu x_{0}}}{\gamma-\frac{1}{2} \mu^{2}} E\left(e^{-\beta \tau^{W^{\mu}}}\right)
$$

In order to inverse the above moment generating function, we just need to inverse the following expressions:

$$
\begin{gathered}
\frac{\mu}{\gamma-\frac{\mu^{2}}{2}}=\int_{0}^{\infty} e^{\mu x} e^{-\sqrt{2 \gamma} x} \mathrm{~d} x-\int_{-\infty}^{0} e^{\mu x} e^{\sqrt{2 \gamma} x} \mathrm{~d} x, \\
\frac{e^{\mu l_{i}}}{\gamma-\frac{\mu^{2}}{2}}=\int_{l_{i}}^{\infty} e^{\mu x} \frac{1}{\sqrt{2 \gamma}} e^{-\sqrt{2 \gamma}\left(x-l_{i}\right)} \mathrm{d} x+\int_{-\infty}^{l_{i}} e^{\mu x} \frac{1}{\sqrt{2 \gamma}} e^{\sqrt{2 \gamma}\left(x-l_{i}\right)} \mathrm{d} x, \\
e^{-n \mu l} e^{\frac{\mu^{2} d}{2}+\mu l_{i}} \mathscr{N}\left(\frac{n l}{\sqrt{d}}-\mu \sqrt{d}\right)=\int_{-\infty}^{l_{i}} e^{\mu x} \frac{1}{\sqrt{2 \pi d}} \exp \left\{-\frac{\left(x+n l-l_{i}\right)^{2}}{2 d}\right\} .
\end{gathered}
$$

Therefor the inversion of $\frac{\mu e^{-n \mu l} e^{\frac{\mu^{2} d}{2}+\mu l_{i}} \mathscr{N}\left(\frac{n l}{\sqrt{d}}-\mu \sqrt{d}\right)}{\gamma-\frac{\mu^{2}}{2}}$ is as follow:
for $x \geq l_{i}$,
$\int_{-\infty}^{l_{i}} \frac{1}{\sqrt{2 \pi d}} \exp \left\{-\frac{\left(y+n l-l_{i}\right)^{2}}{2 d}\right\} e^{-\sqrt{2 \gamma}(x-y)} \mathrm{d} y=\exp \left\{\gamma d-\sqrt{2 \gamma}\left(n l-l_{i}+x\right)\right\} \mathscr{N}\left(\frac{n l-\sqrt{2 \gamma} d}{\sqrt{d}}\right) ;$
for $x<l_{i}$,

$$
\begin{aligned}
& \int_{-\infty}^{x} \frac{1}{\sqrt{2 \pi d}} \exp \left\{-\frac{\left(y+n l-l_{i}\right)^{2}}{2 d}\right\} e^{-\sqrt{2 \gamma}(x-y)} \mathrm{d} y \\
& -\int_{x}^{l_{i}} \frac{1}{\sqrt{2 \pi d}} \exp \left\{-\frac{\left(y+n l-l_{i}\right)^{2}}{2 d}\right\} e^{\sqrt{2 \gamma}(x-y)} \mathrm{d} y \\
= & \exp \left\{\gamma d-\sqrt{2 \gamma}\left(n l-l_{i}+x\right)\right\} \mathscr{N}\left(\frac{x+n l-l_{i}-\sqrt{2 \gamma} d}{\sqrt{d}}\right) \\
& -\exp \left\{\gamma d+\sqrt{2 \gamma}\left(n l-l_{i}+x\right)\right\}\left\{\mathscr{N}\left(\frac{n l+\sqrt{2 \gamma} d}{\sqrt{d}}\right)-\mathscr{N}\left(\frac{x+n l-l_{i}+\sqrt{2 \gamma} d}{\sqrt{d}}\right)\right\}
\end{aligned}
$$

Consequently, we can get Theorem 2.
