# Introduction I : Formulation of the problem

A proper concave function  $U : \mathbb{R}^d \rightarrow [-\infty, \infty)$  is called a utility function supported on  $\mathbb{R}_+^d$  if

- $C_U := \text{cl}(\text{dom}(U)) = \text{cl}\{x : U(x) > -\infty\} = \mathbb{R}_+^d$  and
- $U$  is increasing with respect to  $\mathbb{R}_+^d$ -(partial) order.

Consider the following problem

$$V(x) := \sup\{\mathbb{E}[U(X)] : X \in \mathcal{A}_T^x\}$$

where  $\mathcal{A}_T^x$  is the set of all attainable final gains from an initial portfolio  $x$  (to be defined later). **Main results :**

- 1 Existence of a unique solution under asympt. satiability of value function  $V$
- 2 Multivariate duality à la Kramkov-Schachermayer (1999)
- 3 Including liquidation case, discussion of multivariate RAE

# Introduction II : References

- Davis Norman (1990), Shreve Soner (1994) - BS-type model, intertemporal consumption, stochastic optimal control

# Introduction III : Our contributions

- Cover the case of discontinuous bid-ask processes, i.e. random and discontinuous prop. TC.
- Direct utility function (à la Kamizono), which separates investment and consumption assets in order to include liquidation (not in this talk).
- No restrictions on  $U$  such as  $U(0) = 0$  or  $\sup U(x) = \infty$ . Can treat anything, including  $U(0) = -\infty$ .
- Prove existence of optimizer under the minimal condition of "Asymptotic Satiability" of the value function  $V$ , which is a weaker than RAE.

Main features of the model : all expressed in physical units,  $d$  risky assets (e.g. foreign currencies), the terms of trading are given by a **bid-ask process**  $\{\Pi_t(\omega), t \in [0, T]\}$  : an adapted, càdlàg,  $d \times d$  matrix-valued process s.t.

- $\Pi^{ij} > 0, 1 \leq i, j \leq d$
- $\Pi^{ii} = 1, 1 \leq i \leq d$
- $\Pi^{ij} \leq \Pi^{ik} \Pi^{kj}, 1 \leq i, j, k \leq d$

*Meaning* : To buy 1 unit of currency  $j$  one has to pay  $\Pi_t^{ij}(\omega)$  units of  $i$  (at time  $t$  when the state of world is  $\omega$ )

# TC : Solvency cones & price systems

- *solvency cone*:  $K_t = \text{cone}\{\mathbf{e}^i, \Pi_t^{ij} \mathbf{e}^i - \mathbf{e}^j : 1 \leq i, j \leq d\}$
- *cone of portfolios available at price 0*:  $-K_t$
- *polar of  $-K_t$* :  $K_t^* = \{w \in \mathbb{R}^d : \langle v, w \rangle \geq 0, \forall v \in K_t\}$
- *Financial interpretation*:  $w \in K_t^*$  iff  $w \in \mathbb{R}_+^d$  and  $\Pi_t^{ij} w^i \geq w^j \Rightarrow \Pi_t^{ij} \geq \frac{w^j}{w^i} \Rightarrow \Pi_t^{ij} = (1 + \lambda_t^{ij}) \frac{w^j}{w^i}$  for some  $\lambda_t^{ij} \geq 0$
- Every  $w \in K_t^*$  (resp. in its relative interior) is called *consistent* (resp. *strictly consistent*) *price system*.
- Frictionless case : If  $\Pi_t^{ij} = 1 \quad \forall i, j$ , then  $K_t = \mathbb{R}_+^d$  and  $K_t^* = \{x : x_1 = \dots = x_d \geq 0\}$ .
- Cones ( $K_t$ ) induce the following order : Let  $Y_1, Y_2$  be  $\mathcal{F}_\tau$ -meas. for some stopping time  $\tau$ , then  $Y_1 \succeq_\tau Y_2$  means  $Y_1 - Y_2 \in K_\tau$ .

An  $\mathbb{R}_+^d \setminus \{0\}$ -valued, adapted process  $Z$  is a consistent price process if

- is a càdlàg martingale (*time consistency*)
- $Z_t \in K_t^*, \forall t \in [0, T]$
- If, moreover,  $Z_\tau \in \text{ri}K_\tau^* \ \forall \tau$  stopping time, and  $Z_{\sigma-} \in \text{ri}K_{\sigma-}^* \ \forall \sigma$  predictable s.t.,  $Z$  is called a *strictly* consistent price process.

**Relations with the usual concept of EMM:** choose a numéraire  $Z^1$ , define  $S_t = (1, Z_t^2/Z_t^1 \dots Z_t^d/Z_t^1)$  and set  $d\mathbb{Q}/d\mathbb{P} = Z_T^1/Z_0^1$ , then  $S$  is a  $\mathbb{Q}$ -martingale.

## Main Assumption

**SCPS:** there exists a strictly consistent price process  $Z^s$ .

# Let us come back to max $U$ problem

Let  $U$  denote a utility function such that  $C_U = \mathbb{R}_+^d$ . Our objective is

$$V(x) := \sup\{\mathbb{E}[U(X)] : X \in \mathcal{A}_T^x\}.$$

For stating the main result we need multivariate Inada's conditions :

- *Essentially smoothness* (analogue of  $U'(0) = \infty$ )
- *Asymptotic satiability* (analogue of  $U'(\infty) = 0$ )

## Definition

A utility function  $U : \mathbb{R}^d \rightarrow [-\infty, \infty)$  is said to be *essentially smooth* if

- 1  $U$  is differentiable in the interior of  $\mathbb{R}_+^d$ ;
- 2  $\lim_{i \rightarrow \infty} |\nabla U(x_i)| = +\infty$  for any  $x_i \in \mathbb{R}_+^d$  converging to a boundary point of  $\mathbb{R}_+^d$ .

# Asymptotic satiability : $U'(\infty) = 0$

- Let  $U$  be a utility function, and let  $C_U$  be its support cone. We say that a utility function  $U$  is *asymptotically satiable* if given any  $\epsilon > 0$  there exists an  $x \in \text{dom}(U)$  such that

$$\partial U(x) \cap [0, \epsilon]^d \neq \emptyset.$$

- Recall that the dual function of  $U$  is defined by

$$U^*(x^*) = \sup_{x \in \mathbb{R}^d} \{U(x) - \langle x, x^* \rangle\}$$

- One can prove that asympt. satiability of  $U$  is equivalent to  $0 \in C_{U^*} := \text{cl}(\text{dom}(U^*))$ .

# Asymptotic satiability : $U'(\infty) = 0$

- Let  $U$  be a utility function, and let  $C_U$  be its support cone. We say that a utility function  $U$  is *asymptotically satiable* if given any  $\epsilon > 0$  there exists an  $x \in \text{dom}(U)$  such that

$$\partial U(x) \cap [0, \epsilon]^d \neq \emptyset.$$

- Recall that the dual function of  $U$  is defined by

$$U^*(x^*) = \sup_{x \in \mathbb{R}^d} \{U(x) - \langle x, x^* \rangle\}$$

- One can prove that asympt. satiability of  $U$  is equivalent to  $0 \in C_{U^*} := \text{cl}(\text{dom}(U^*))$ .

# Asymptotic satiability : $U'(\infty) = 0$

- Let  $U$  be a utility function, and let  $C_U$  be its support cone. We say that a utility function  $U$  is *asymptotically satiable* if given any  $\epsilon > 0$  there exists an  $x \in \text{dom}(U)$  such that

$$\partial U(x) \cap [0, \epsilon]^d \neq \emptyset.$$

- Recall that the dual function of  $U$  is defined by

$$U^*(x^*) = \sup_{x \in \mathbb{R}^d} \{U(x) - \langle x, x^* \rangle\}$$

- One can prove that asympt. satiability of  $U$  is equivalent to  $0 \in C_{U^*} := \text{cl}(\text{dom}(U^*))$ .

# Main result

Assume that  $V(x) < \infty$  for some  $x \in \text{int}(\text{dom } V)$

## Theorem

Suppose that  $U : \mathbb{R}^d \rightarrow [-\infty, \infty)$  is a utility function supported on  $\mathbb{R}_+^d$ , essentially smooth, strictly concave on  $\mathbb{R}_{++}^d$ , and asymptotically satiable.

Suppose in addition **one of the following conditions** :

- 1  $V$  is asymptotically satiable
- 2  $U^*$  satisfies the growth condition

$$U^*(\epsilon x^*) \leq \zeta(\epsilon)(U^*(x^*)^+ + 1)$$

for all  $x^* \in \mathbb{R}_{++}^d$ ,  $\epsilon \in (0, 1]$  and for some positive function  $\zeta$  (stronger than 1)

Then the optimal investment problem has a unique solution  $\hat{X}_x$ .

## Lemma

Let  $U$  be a utility function with  $C_U = \mathbb{R}_+^d$ , essentially smooth, strictly concave on  $\mathbb{R}_{++}^d$ , multivariate risk averse and asympt. satiable.

Suppose that  $U$  is bounded below and satisfies multiv. RAE. Then  $U^*$  satisfies the growth condition, i.e. there exists a function  $\zeta : (0, 1] \rightarrow [0, \infty)$  such that for all  $\epsilon \in (0, 1]$  and all  $x^* \in \mathbb{R}_{++}^d$

$$U^*(\epsilon x^*) \leq \zeta(\epsilon)(U^*(x^*)^+ + 1).$$

## Proposition (Lagrange Duality Theorem)

1 If  $x \in \text{int}(C_V)$  then

$$\sup_{X \in \mathcal{C}} \mathbb{U}_x(X) = V(x) = \min_{m \in \mathcal{D}} \mathbb{U}_x^*(m) \in \mathbb{R}.$$

2 If  $x \notin C_V$  then

$$\sup_{X \in \mathcal{C}} \mathbb{U}_x(X) = V(x) = \inf_{m \in \mathcal{D}} \mathbb{U}_x^*(m) = -\infty.$$

In the first case we let  $\hat{m} \in \mathcal{D}$  denote the minimizer. Then

$$\hat{X} := -\nabla U^* \left( \frac{d\hat{m}^c}{d\mathbb{P}} \right)$$

is the optimizer for the primal problem.

# Duality IV : Sketch of the proof

Any candidate optimizer  $\hat{X}$  must satisfy

1  $U(\hat{X}) = U^* \left( \frac{d\hat{m}^c}{dP} \right) + \left\langle \hat{X}, \frac{d\hat{m}^c}{dP} \right\rangle;$

2  $\hat{X} \in \mathcal{A}_T^x$ ; and

3  $E \left[ \left\langle \hat{X}, \frac{d\hat{m}^c}{dP} \right\rangle \right] = \hat{m}(x).$

These are equivalent to

1  $\hat{X} = \left( -\nabla U^* \left( \frac{d\hat{m}^c}{dP} \right), \underline{0} \right)$ ; and

2  $E \left[ \left\langle \hat{X}, \frac{d\hat{m}^c}{dP} \right\rangle \right] \leq m(x) \quad \forall m \in \mathcal{D},$  with equality for  $m = \hat{m}(x).$  See C. & Schachermayer (2006)

Take 1 as definition of  $\hat{X}$ . We prove 2 by variational analysis, here the asymptotic satiability of  $V$  turns out to be crucial.

# Duality IV : Sketch of the proof

Any candidate optimizer  $\widehat{X}$  must satisfy

1  $U(\widehat{X}) = U^* \left( \frac{d\widehat{m}^c}{dP} \right) + \left\langle \widehat{X}, \frac{d\widehat{m}^c}{dP} \right\rangle;$

2  $\widehat{X} \in \mathcal{A}_T^x$ ; and

3  $E \left[ \left\langle \widehat{X}, \frac{d\widehat{m}^c}{dP} \right\rangle \right] = \widehat{m}(x).$

These are equivalent to

1  $\widehat{X} = \left( -\nabla U^* \left( \frac{d\widehat{m}^c}{dP} \right), \underline{0} \right)$ ; and

2  $E \left[ \left\langle \widehat{X}, \frac{d\widehat{m}^c}{dP} \right\rangle \right] \leq m(x) \quad \forall m \in \mathcal{D},$  with equality for  $m = \widehat{m}(x).$  See C. & Schachermayer (2006)

Take 1 as definition of  $\widehat{X}$ . We prove 2 by variational analysis, here the asymptotic satiability of  $V$  turns out to be crucial.

# The liquidation case : consumption vs investment assets

$$\bar{U}(x) := \sup\{\tilde{U}(\xi) : (\xi, 0) \in L_+^0(x - K_T)\}, \quad x \in \mathbb{R}^d$$

- Notice that  $\bar{U}(x) = \tilde{U}(I(x))$  where  $I(\cdot)$  is the liquidation function expressed in *physical units*, i.e.

$$I(x) = \sup \{ \xi \in L^0(\mathbb{R}_+) : (\xi, 0) \in L_+^0(x - K_T) \}.$$

- One can prove that

$$\sup_{X \in \mathcal{A}_T^x} E[U(X)] = \sup_{X \in \mathcal{A}_T^x} E[\tilde{U}(I(X_{T-}))].$$
